

A Transferrin (Benjamin 2014, n = 23,986)

B Circulating total-tau (Sarnowski 2022, n = 14,721)

PP.H4 = 0.447 is below the conventional 0.8 threshold; the conditional H4/(H3+H4) = 96.3% is reported because the residual mass sits on PP.H1 (transferrin-only), reflecting limited power in the tau GWAS at this locus (min $p \approx 0.0014$), not evidence against colocalization (PP.H3, distinct causal variants, ≈ 0.02).

In panel B the regional lead variant is rs3811658 (green); rs8177240 (red) is the top PP.H4 variant and ranks third in the tau GWAS. The two are 849 bp apart and in near-complete linkage disequilibrium ($r^2 = 0.974$).
